Abstract

In this paper, based on the contributions of Tucker (1983) and Sebő (1992), we generalize the concept of a sequential coloring of a graph to a framework in which the algorithm may use a coloring rule-base obtained from suitable forcing structures. In this regard, we introduce the *weak* and *strong sequential defining numbers* for such colorings and as the main results, after proving some basic properties, we show that these two parameters are intrinsically different and their spectra are nontrivial. Also, we consider the natural problems related to the complexity of computing such parameters and we show that in a variety of cases these problems are **NP**-complete. We conjecture that this result does not depend on the rule-base for all nontrivial cases.

1 Introduction

Graph coloring, as a special case of the graph homomorphisms problem, is widely known to be among the most fundamental problems in graph theory and combinatorics. On the other hand, a long list of applications of the problem within and out of graph theory itself, not only adds to the importance of the problem, but also, asks for efficient and easy-to-use solutions in different cases (e.g. see [13, 18, 19]). Unfortunately, based on some recent deep nonapproximability results (e.g. among other references see [1, 16] for the applications of the PCP theorem), it is known that the coloring problem is among the hardest problems in **NP** and does not admit an efficient solution/approximation, unless $\mathbf{P} = \mathbf{NP}$ (or similar coincidence for randomized classes as **RP**). Therefore, it is quite important, at least as far as the applications are concerned, to acquire a good understanding of the coloring structures of graphs, and to develop efficient algorithms for the tractable cases.

Sequential coloring of a given graph is an alternative approach to the classical coloring problem that may not lead to the same solution (e.g. see [17, 23, 24, 25]), however, based on the algorithm and its rule-base, it is conceivable to seek a set of vertices with preset colors that guides the algorithm to the ideal solution. This approach not only can be considered as a partial solution to the original problem, but also will give rise to a hierarchy of graphs, based on their coloring structures, which is ordered using the rule-base of the algorithm.

¹Correspondence should be addressed to daneshgar@sharif.ir.

Probably, the most popular algorithm of this type is the so-called *greedy algorithm* that uses the very simple (and independent of the structure) rule of setting the first color available, regardless of the neighborhood structure of the vertex visited. Our approach in this paper, is to enhance such an algorithm to be able to use a local coloring rule-base, depending on the neighborhood structure of the vertices, and use these rule-bases to introduce a hierarchy of graphs based on their coloring structures. To the best of authors' knowledge, *sequential coloring* of graphs is formally first introduced by A. Tucker in [25] to study perfect graphs and is also studied afterwards (Particularly, see [24] for a very interesting application and connections to other classes of graphs as perfect and uniquely colorable graphs). The very closely related concept of *online coloring* of graphs in which one assumes that the vertices are ordered (say $\{v_1, \dots, v_n\}$) and the algorithm at the k 'th vertex v_k is only informed about the data of vertices $\{v_1, \dots, v_{k-1}\}$, is also extensively studied for its important applications in real industrial problems, where the greedy version is sometimes called the *first fit* or *Grundy* coloring. However, in sequential coloring of graphs, we assume that the algorithm at each vertex is informed about the structure and the data of a neighborhood of the vertex (regardless of the indices). Therefore, from an algorithmic point of view, the main difference between the online and the sequential approaches falls in the way that the algorithm is informed about the structure of the graph. In this article we concentrate on the concept of sequential coloring of graphs, while most of the results can be extended to the online version applying the necessary modifications.

In our approach, we generalize the sequential model in two ways. Firstly, we let the algorithm have access to a neighborhood of radius d of each vertex, where d is a constant of the algorithm, and secondly, we confine the coloring rules of the algorithm to be only accessible through a fixed rule-base $\mathcal{R}$. Such rule-bases are introduced by using the concept of a *forcing structure* discussed in Section 1.1 (see [3, 4, 5, 6, 7, 8] for the background). Our results in this section show that there is a general machinery to generate a variety of rule-bases to match the user's needs.

Our main objective in this paper is to study the defining sets of sequential colorings of graphs and analyze the computational complexity of the related problems. As a brief historical note we may note that the concept of a defining set of graph colorings is extensively studied (e.g. see [14]), specially for the case of Cartesian product of complete graphs which is essentially what is already known as critical sets of Latin squares (e.g. see [2, 20, 21]). To the best of the first author's knowledge, the concept of an online critical set for a Latin square is first introduced by E. Mendelsohn (the first author heard about this from E. Mendelsohn during meetings and talks at Sharif University of Technology on November 1998). The concept was soon generalized to the concept of a defining set of an online graph coloring by M. Zaker and the first results on these are published by him (see [26, 28, 29, 30, 31]).

As far as we are aware, the concept of a defining set of sequential colorings of a graph is first introduced by the first author and it is appeared in the main result of [12], where it is proved that any boolean function can be simulated by a graph, where to compute the function for some given values, one may use the values as colors of a defining set of a sequential coloring of the corresponding graph.

Needless to say, the contributions of A. Tucker and A. Sebő ought to be considered

as the origins of sequential colorings of graphs, however the approach in [12] and in this paper is mainly inspired by the applications of the concept of *effective* defining sets in cryptography (also see [32]). Therefore, in the rest of this section we present a short overview of the contributions of A. Tucker and A. Sebő and we also provide the basic concepts we need in the rest of the article, namely *forcing structures* and *graph amalgams*.

In Section 2 we precisely define the concept of a *sequential coloring* of a graph, as well as the spectra of *weak* and *strong defining numbers*, and moreover, we prove some basic results in this regard. Specially, among our main results in this section we show that the two concepts of *weak* and *strong* defining numbers are intrinsically different (Theorem 1) and also we show that each spectrum is completely nontrivial (Theorem 2).

Our main contribution in Section 3 are a couple of **NP**-completeness results (generally) stating that computation of weak and strong defining numbers are **NP**-complete problems. Although we have not been able to obtain efficient and easy to present proofs for the fact that the **NP**-completeness result does not depend on the rule-base *in general*, we strongly believe that this is the case for almost all nontrivial cases, where Theorems 3, 4 and 5 as the main results of this section are positive justifications in this regard.

Throughout the paper we will be considering finite simple graphs. The vertex set of a graph G is denoted by $V(G)$ and the edge set by $E(G)$, and for any subset $A \subseteq V(G)$ the notation $G[[A]]$ stands for the vertex induced subgraph on A . An edge with two end vertices u and v is denoted by uv and $N_G(v) \stackrel{\text{def}}{=} \{u \in V(G) \mid uv \in E(G)\}$ is the set of neighbours of the vertex v in G . Throughout the paper, $|A|$ denotes the size of the set A . Also, K_n is the complete graph on n vertices and $cl(G)$ is the clique number of the graph G . A graph G is said to be *t-colorable* if it admits a proper vertex t -coloring. Also, G is said to be *t-chromatic* if $t = \chi(G)$, where $\chi(G)$ is the ordinary chromatic number of G . For basic concepts of graph theory we refer to [27].

In what follows we recall a more or less standard notation for amalgams which is adopted from [12] (the interested reader may also consult [12] for more on this or read the Appendix of this article).

Let $X = \{x_1, x_2, \dots, x_k\}$ and G be a set and a graph, respectively, and also, consider a one-to-one map $\varrho : X \longrightarrow V(G)$. Evidently, one can consider ϱ as a graph monomorphism from the empty graph X on the vertex set X to the graph G , where in this setting we interpret the situation as a *labeling* of some vertices of G by the elements of X . The data introduced by (X, G, ϱ) is called a *marked graph* G marked by the set X through the map ϱ . Note that (by abuse of language) we may introduce the corresponding marked graph as $G[x_1, x_2, \dots, x_k]$ when the definition of ϱ (especially its range) is clear from the context. Also, (by abuse of language) we may refer to *the vertex* x_i as the vertex $\varrho(x_i) \in V(G)$. This is most natural when $X \subseteq V(G)$ and vertices in X are marked by the corresponding elements in $V(G)$ through the identity mapping. We use the following notation

$$G[x_1, x_2, \dots, x_k] + H[y_1, y_2, \dots, y_l]$$

for the graph (informally) constructed by taking the disjoint union of the marked graphs $G[x_1, x_2, \dots, x_k]$ and $H[y_1, y_2, \dots, y_l]$ and then *identifying* the vertices with the same mark (for a formal and precise definition see the Appendix). It is understood that a repeated appearance of a graph structure in an expression as $G[v] + G[v, w]$ is always considered as different isomorphic copies of the structure marked properly by the indicated labels (e.g. $G[v] + G[v, w]$ is an amalgam constructed by two different isomorphic copies of G identified on the vertex v where the vertex w in one of these copies is marked).

By $K_k[v_1, v_2, \dots, v_k]$ we mean a k -clique on $\{v_1, v_2, \dots, v_k\}$ marked by its own set of vertices. Specially, a single edge is denoted by $\varepsilon[v_1, v_2]$ (i.e., $\varepsilon[v_1, v_2] = K_2[v_1, v_2]$). As one more simple example note that $\varepsilon[v_1, v_2] + \varepsilon[v_2, v_3]$ is a path of length 2 on the vertex set $\{v_1, v_2, v_3\}$.

1.1 Forcing in graph coloring

Given a graph G , consider a set $\mathcal{L} = \{L_v\}_{v \in V(G)}$ with $L_v \subseteq \{1, \dots, t\}$ such that $t \geq \chi(G)$ is a fixed integer. Hereafter,

$$\|\mathcal{L}\| \stackrel{\text{def}}{=} \sum_{v \in V(G)} |L_v|.$$

The list coloring problem, $(G, \mathcal{L}, t)$, is to find a coloring $\sigma : V(G) \rightarrow \{1, \dots, t\}$ such that for all pairs of distinct vertices u and v ,

$$(\sigma(v) \in L_v) \quad \text{and} \quad (uv \in E(G) \Rightarrow \sigma(u) \neq \sigma(v)).$$

To see that this can also be viewed as an embedding problem, assume that the list coloring problem $(G, \mathcal{L}, t)$ is given, and let $H = G \cup K_t$ with $V(K_t) = \{v_1, \dots, v_t\}$. Also, assume that (without loss of generality) we have fixed the colors of vertices $V(K_t) = \{v_1, \dots, v_t\}$ such that v_i has taken the color i for all $i \in \{1, \dots, t\}$. Now, one may construct a new graph, $\tilde{H}_{G, \Phi, t}$, such that for each $u \in V(G)$ and $L_u \in \mathcal{L}$ we add new edges $\Phi_u = \{uv_i\}_{i \notin L_u}$ to the graph H . If

$$\Phi \stackrel{\text{def}}{=} \bigcup_{u \in V(G)} \Phi_u,$$

then it is clear that there is a one-to-one correspondence between the set of t -colorings of the graph $\tilde{H}_{G, \Phi, t}$ and the set of solutions (t -colorings) of the list coloring problem $(G, \mathcal{L}, t)$ (given by restriction). A graph G is called uniquely $\mathcal{L}$ -list-colorable, if the list coloring problem, $(G, \mathcal{L}, t)$, on G with lists $\mathcal{L} = \{L_v\}_{v \in V(G)}$ has a unique solution. Also, when the lists are all equal to the set $\{1, \dots, t\}$, such a graph is called a uniquely t -colorable graph or a t -UCG for short if the list coloring problem has a unique solution up to permutation of colors which means that the color classes are fixed for all solutions. For more on this subject see [11, 19].

Hereafter, we will freely switch between the embedding setup and the list coloring approach. Also, we write $\mathcal{L} \subseteq \mathcal{L}'$ as a shorthand for $L_v \subseteq L'_v$ for all v .

Consider a list coloring problem $(H, \mathcal{L}, t)$, and a subgraph $G \leq H$ such that

$$A \stackrel{\text{def}}{=} \bigcup_{u \in V(G)} L_u, \quad \text{and} \quad |A| = k \leq t,$$

Figure 1: A minimal 3-UCG (see Examples 1 and 2).

where the list coloring problem $(G, \mathcal{L}, k)$ has a unique solution (up to permutation of colors). Then for any vertex $v \notin V(G)$ whose neighborhood in G intersects all color-classes of $(G, \mathcal{L}, k)$, one may replace L_v by $L_v - A$ without any change in the solution-set of the list coloring problem $(H, \mathcal{L}, t)$. Such a situation is called a *type 1 forcing* on v by G [3, 4, 5, 8]. Note that a special case of this situation is when $G \leq H$ is a k -UCG.

Example 1. Consider the minimal 3-UCG of Figure 1, and let's try to find a 3-coloring σ of it. It is quite easy to see that without loss of generality we have

$$\sigma(v_1) = \sigma(v_4) = 1, \quad \sigma(v_2) = 2 \quad \text{and} \quad \sigma(v_3) = 3.$$

Then it is clear that the set of possible colors for both of the vertices v_5 and v_6 is $\{2, 3\}$, and consequently, by a type 1 forcing on the K_2 -clique induced on $\{v_5, v_6\}$ we have $\sigma(v_7) = 1$. ♣

Let us recall the following definition and theorem from [6]. For a $(t - 1)$ -chromatic graph G , a list (repetition is allowed)

$$\mathcal{F} = \{(i, W_i) \mid 1 \leq i \leq l\}$$

with $W_i \subseteq V(G)$ is called a *transverse system* for G if either

$$G = K_{t-1} \quad \& \quad \mathcal{F} = \{(1, V(G))\},$$

or both of the following conditions are satisfied;

- For every $(t - 1)$ -coloring σ of G , if $(i, W) \in \mathcal{F}$ then W has nonempty intersection with all color-classes of σ .
- For every t -coloring $\sigma : V(G) \xrightarrow{\text{onto}} \{1, \dots, t\}$ of G , there exists $(i, W) \in \mathcal{F}$ such that W has nonempty intersection with all color-classes of σ .

Theorem A. [6] *Let H be a t -chromatic graph such that in every t -coloring of H there is a fixed color-class V^* consisting of m specified vertices $v_1, \dots, v_m$, ($m \geq 1$); and consider $G = H - V^*$. Also define $\mathcal{F} = \{(i, N_G(v_i)) \mid v_i \in V^*\}$. Then,*

a) $\chi(G) = t - 1$ and $\mathcal{F}$ is a transverse system for G .

Moreover if $cl(H) \leq t - 1$ then,

b) $cl(G[[W]]) \leq t - 2$ for every $(i, W) \in \mathcal{F}$, and $cl(G) \leq t - 1$.

Conversely, let G be a $(t - 1)$ -chromatic graph and let $\mathcal{F} \subseteq \mathbf{N} \times 2^{V(G)}$ be a transverse system for G . Then the graph H obtained by adding to G new vertices v_i , for each $((i, W_i) \in \mathcal{F})$, and joining each v_i to all vertices in W_i is a t -chromatic graph such that in any one of its t -colorings the class $V^* = \{v_i \mid (i, W_i) \in \mathcal{F}\}$ is fixed. If in addition (b) is also fulfilled then $cl(H) \leq t - 1$.

Consider a list coloring problem $(M, \mathcal{L}, l)$, and subgraphs $G \leq H \leq M$, with $V^* \stackrel{\text{def}}{=} V(H) - V(G)$, such that G and H satisfy all conditions of Theorem A. Then one may replace the lists of all vertices in V^* by

$$L \stackrel{\text{def}}{=} \bigcap_{u \in V^*} L_u,$$

without any change in the solution-set of the list coloring problem $(H, \mathcal{L}, l)$. Such a situation is called a *type 2 forcing* on V^* by G [3, 4, 5, 8]. Note that a special case of this situation is when H is a t -UCG.

Example 2. Again, consider the minimal 3-UCG of Figure 1, and let's try to find a 3-coloring σ of it. It is quite easy to see that without loss of generality we have

$$\sigma(v_1) = 1, \quad \sigma(v_2) = 2 \quad \text{and} \quad \sigma(v_3) = 3.$$

Then it is clear that the set of possible colors for the vertex v_5 is $\{2, 3\}$ and the set of possible colors for the vertex v_8 is $\{1, 2\}$. Now, by a type 2 forcing on the subgraph induced on $\{v_5, v_6, v_7, v_8\}$, in which both v_5 and v_8 have the same color in any 3-coloring, we may replace the list of colors of these vertices by the intersection, which shows that,

$$\sigma(v_5) = \sigma(v_8) = 2.$$

Hence, using type 1 and 2 forcings along with a suitably chosen uniquely colorable graph one may construct a variety of forcing structures to analyze or construct new coloring structures.

1.2 Sequential coloring and perfect graphs

In [25] Tucker introduces an algorithmic approach to the Strong Perfect Graph Conjecture. He calls a t -UCG, G , *sequentially t -colorable*, if the n vertices of G can be indexed as $v_1, \dots, v_n$ such that $v_1, \dots, v_t$ are in a clique (and initially are arbitrarily given different colors) and after $v_1, \dots, v_{m-1}$ ($m > t$) are colored, v_m has a *forced* coloring by one of the following sequential coloring rules.

- 1) If v_m is adjacent to previously colored vertices of $t - 1$ (but not t) different colors, then v_m must be given the one color not used by its previously colored neighbors.

- 2) If v_j and v_m , ($j < m$), are each adjacent to all vertices of a clique of size $t - 1$ (but v_j and v_m are not adjacent to each other), then v_m must be given the same color as v_j .
- 3) If all vertices of color i have been sequentially colored (using rules 1 and 2), these vertices can be deleted and t can be reduced by one in subsequent use of rules 1 and 2.

Tucker also calls a t -UCG *strongly sequentially t -colorable* if it can be sequentially colored starting from any t -clique and using only rule 1. In these directions he proves

Theorem B. [25] *If G is a comparability graph or the complement of a comparability graph, then G is uniquely t -colorable if and only if G is sequentially t -colorable.*

Theorem C. [25] *If G is a chordal graph or the complement of a chordal graph, then G is uniquely t -colorable if and only if G is sequentially t -colorable.*

Tucker also proposes the following conjecture.

Conjecture 1. [25] *For perfect graphs, unique t -colorability is equivalent to sequential t -colorability.*

It is known that $G - v$ is a uniquely colorable graph for any minimal imperfect graph G and any one of its vertices v . A well-known approach to the Strong Perfect Graph Conjecture (SPGC) is to study the following two problems:

- Prove the existence of Tucker forcing structures in uniquely colorable perfect graphs, and specially in cases where the graph is obtained from a minimal imperfect graph by excluding one of the vertices.
- Prove that a minimal imperfect graph with enough Tucker forcing structures is either an odd hole or an antihole.

For more on this the reader may refer to [15, 22, 24] where in [24], among other results, some nice reformulations of SPGC in relation with Tucker's forcing structures and unique colorability are given.

2 Sequential coloring of ordered list-graphs

Definition 1. Any marked graph $\varrho : \{1, 2, \dots, |V(G)|\} \longrightarrow G$ will be called an *ordered* graph and will be denoted in an abbreviated style as $G[\varrho]$ or $G[n]$ when $|V(G)| = n$ and ϱ is clear from the context (usually assumed to be $i \mapsto v_i$).

Let t be a fixed integer and $\mathcal{L} = \{L_1, L_2, \dots, L_n\}$ be a set of lists for which $L_i \subseteq \{1, 2, \dots, t\}$ for each i . Then a graph G with $n = |V(G)|$ marked by $\mathcal{L}$ is called a *list-graph* and is denoted by $G[\mathcal{L}]$ (when we assume that the mapping is $L_v \mapsto v$). Similarly, a graph G marked by a set $\{(1, L_1), (2, L_2), \dots, (n, L_n)\}$ is called an *ordered list-graph* and is denoted by $G[n, \mathcal{L}]$.

In all cases G will be referred to as the *base-graph*. Also, when the list assignment

$\mathcal{L}$ determines a proper coloring γ of $G[n]$ (i.e. for any vertex v we have $|L_v| = 1$) then $G[n, \gamma]$ is called an *ordered colored-graph*¹. ♠

Definition 2. A *local t -coloring rule* R on the base-graph H is an updating rule for the lists of a list-graph $H[\mathcal{L}]$ that changes it to a new list-graph $H[\mathcal{L}']$ in which the base-graph is not changed and,

- a) For each vertex $v \in V(H)$ we have $L'_v \subseteq L_v$.
- b) The list coloring problems $(H[\mathcal{L}], t)$ and $(H[\mathcal{L}'], t)$ have the same set of solutions.
- c) If using R , $H[\mathcal{L}_1]$ is changed to $H[\mathcal{L}'_1]$, $H[\mathcal{L}_2]$ is changed to $H[\mathcal{L}'_2]$ and $\mathcal{L}_1 \subseteq \mathcal{L}_2$ then $\mathcal{L}'_1 \subseteq \mathcal{L}'_2$.

Such a replacement of lists is usually denoted as

$$R : \quad \textbf{condition} \quad \Rightarrow \quad L \leftarrow L'$$

which means that the list L is replaced by the list L' if **condition** is satisfied. ♠

Note that a standard way of constructing such coloring rules is through constructing forcing structures, e.g. type 1 or type 2 forcing introduced in Section 1.1. In what follows we formulate a couple of well-known rules based on what has already been discussed in previous sections.

Example 3. The following rule is called the Tucker's first rule, and is denoted by R_1^{Tu} (see Section 1.2 for motivations).

$$\left(\exists t > 1, \quad |A| \stackrel{\text{def}}{=} \left| \bigcup_{x_t \neq x_i \in V(K_t[x_1, x_2, \dots, x_t])} L_{x_i} \right| = t - 1 \right) \Rightarrow (L_{x_t} \leftarrow L_{x_t} - A). \quad (1)$$

Note that Tucker's first rule is a type 1 forcing on a clique. Also, define $T_t^2[u, v]$ as follows,

$$T_t^2[u, v, x_1, x_2, \dots, x_{t-1}] \stackrel{\text{def}}{=} K_t[u, x_1, x_2, \dots, x_{t-1}] + K_t[v, x_1, x_2, \dots, x_{t-1}].$$

Also, the following rule is called the Tucker's second rule, and is denoted by R_2^{Tu} (see Section 1.2 for motivations).

$$\left(\exists t > 1, \quad \left| \bigcup_{w \in V(T_t^2[u, v, x_1, x_2, \dots, x_{t-1}])} L_w \right| = t \right) \Rightarrow (L_u \leftarrow L_u \cap L_v). \quad (2)$$

It is also clear that Tucker's second rule is a type 2 forcing on a clique. ♣

¹Note that considering the contents of the previous section, and by abuse of notation, e.g. $G[\varrho, \gamma][u, v]$, stands for a *marked, ordered and colored* graph where the ordering ϱ , the coloring γ and marks u, v are clear from the context.

Hereafter, we adopt the notation $\mathcal{R}_T \stackrel{\text{def}}{=} \{\mathcal{R}_1^{T_u}, \mathcal{R}_2^{T_u}\}$. Moreover, we refer to a such an specific rule as $\mathcal{R}_1^{T_u}(t_0)$ for some $t = t_0$. It is also instructive to consider the special case of $t = 2$ for both Tucker rules. Note that in the first case, $\mathcal{R}_1^{T_u}(2)$ states (the well-known and simple rule) that, in any coloring problem, if one end of an edge has a fixed color, then this color may be excluded from the list of the other end of this edge. This can be considered as the most natural coloring rule coming directly from the definition of a *proper coloring* of a graph, and consequently, from now on, we assume that $\mathcal{R}_1^{T_u}(2)$ is contained in any coloring rule-base.

Also, $\mathcal{R}_2^{T_u}(2)$ states that in a 2-coloring of a path of length two, both vertices of degree one must have the same color.

Definition 3. A t -coloring rule-base $\mathcal{R}$, with $r \geq 0$ structural rules and the non-structural rule $\mathcal{R}^*$, is a finite set

$$\mathcal{R} \stackrel{\text{def}}{=} \{\mathcal{R}_1, \mathcal{R}_2, \dots, \mathcal{R}_r\} \cup \{\mathcal{R}^*\}$$

such that,

- For each $1 \leq i \leq r$, $\mathcal{R}_i$ is a local t -coloring rule on a base-graph H_i .
- The nonstructural rule $\mathcal{R}^*$ is a coloring procedure to change a list $L \subseteq \{1, 2, \dots, t\}$ to a list $L' \subseteq L$ that must be compatible with $\mathcal{R}_1^{T_u}(2)$. This rule may not satisfy properties (b) and (c) of Definition 2.

A t -coloring rule-base is said to be *d-bounded*, if for every $1 \leq i \leq r$, the diameter of the base-graph H_i , of the local rule $\mathcal{R}_i$, is not greater than the constant d . A t -coloring rule-base is said to be *structural*, if it consists, only, of structural rules. ♠

Example 4. A standard example for the nonstructural coloring rule $\mathcal{R}^*$, is the *greedy* coloring rule, $\mathcal{R}^{Gr}$, which is defined as follows,

$$\mathcal{R}^{Gr} : \left(A \stackrel{\text{def}}{=} \bigcup_{x \in N(u) \text{ \& } |L_x|=1} L_x \right) \Rightarrow (L_u \leftarrow \{\min(L_u - A)\}). \quad (3)$$

Hereafter, $\mathcal{R}_G \stackrel{\text{def}}{=} \{\mathcal{R}^{Gr}\}$. ♣

Definition 4. If $\mathcal{R}$ is a d -bounded t -coloring rule-base, then the list coloring problem $(G[n], \mathcal{L}, t)$ is said to be $(\mathcal{R}, d, r)$ -solvable if the following algorithm,

OLG- $\mathcal{R}$ -Col: $(G[n], \mathcal{L}, t, d, \text{rounds}, \text{Done})$,

ends up with a t -coloring of $G[n]$ as a solution with $\text{Done} = \text{true}$, $\text{rounds} < r$, where rounds returns the number of rounds that the algorithm has scanned the graph and the *returned* list assignment $\mathcal{L}$ is a proper coloring of $G[n]$ such that for any vertex v we have $|L_v| = 1$.

OLG- $\mathcal{R}$ -Col: $(G[n], \mathcal{L}, t, d, rounds, Done)$

- 0) $rounds := 0, Done := True,$
- 1) $colored := True,$
- 2) **For** i from 1 to n do
 - Local- $\mathcal{R}$ -Update** $(G[n], \mathcal{L}, t, v_i, d, Done, Col),$
 - If** (NOT $Done$) **Then** Halt and write(Failure),
 - If** (NOT Col) **Then** $colored := False,$
 - End** (For),
- 3) $rounds := rounds + 1,$
- 4) **If** (NOT $colored$) **Then** goto: (1)
- Else** Halt and write the coloring,

End (OLG- $\mathcal{R}$ -Col).

The procedure **Local- $\mathcal{R}$ -Update** locally updates the lists according to the rule-base of the algorithm and, moreover, we assume that this is done in a *canonical order*. In more details we have,

Local- $\mathcal{R}$ -Update: $(G[n], \mathcal{L}, t, v, d, Done, Col)$

- 0) $Col := True,$
- 1) Focus on a d -neighborhood of v in G and update the list of v using the local rules (R_i 's) in $\mathcal{R}$ and all subgraphs of the neighborhood (in a canonical ordering).
- 2) Update the list of v using R^* (if any such rule exists in the rule-base),
- 3) **If** $|L(v)| = 0$ **Then** $Done := False,$
- 4) **If** $|L(v)| \neq 1$ **Then** $Col := False,$

End (Local- $\mathcal{R}$ -Update).

A list coloring problem $(G[n], \mathcal{L}, t)$ is said to be $(\mathcal{R}, d)$ -solvable if it is $(\mathcal{R}, d, \infty)$ -solvable (which means that it is $(\mathcal{R}, d, r)$ -solvable for some natural number r). ♠

2.1 Sequential defining sets

Definition 5. Given a t -coloring γ of a graph G , and a subset $A \subset V(G)$ then the list assignment $\mathcal{L}^{A, \gamma}$ is defined as follows,

$$\mathcal{L}_v^{A, \gamma} \stackrel{\text{def}}{=} \begin{cases} \{\gamma(v)\} & v \in A \\ \{1, 2, \dots, t\} & v \notin A. \end{cases}$$

Given an ordered colored-graph $G[n, \gamma]$, a subset $A \in V(G)$ is called an *sequential $\mathcal{R}$ -defining set* (or an $\text{sds}_{\mathcal{R}}$ for short) for $G[n, \gamma]$ with respect to the d -bounded t -coloring rule-base $\mathcal{R}$, if the list coloring problem $(G[n], \mathcal{L}^{A, \gamma}, t)$ is $(\mathcal{R}, d)$ -solvable, and returns the coloring γ . In that case, the number

$$\iota_{G[n, \gamma], \mathcal{R}}(A) \stackrel{\text{def}}{=} |A| + rounds - 1$$

is called the *index* of A with respect to $G[n, \gamma]$.

The subset $A \subseteq V(G)$ is called a *weak minimum sequential $\mathcal{R}$ -defining set* (or a $\text{Wmsds}_{\mathcal{R}}$) for $G[n, \gamma]$ with respect to the d -bounded t -coloring rule-base $\mathcal{R}$ (or a $\text{Wmsds}(G[n, \gamma], \mathcal{R})$ for short), if A is an $\text{sds}_{\mathcal{R}}$ for $G[n, \gamma]$ of minimum size.

Also, a *strong minimum sequential $\mathcal{R}$ -defining set* (or a $\text{Smsds}_{\mathcal{R}}$) for $G[n, \gamma]$ with respect to the d -bounded t -coloring rule-base $\mathcal{R}$ (or a $\text{Smsds}(G[n, \gamma], \mathcal{R})$ for short), is an $\text{sds}_{\mathcal{R}}$ for $G[n, \gamma]$ of minimum index. The minimum numbers are called the *weak sequential defining number* and the *strong sequential defining number* of $G[n, \gamma]$ with respect to the d -bounded t -coloring rule-base $\mathcal{R}$, and are denoted by $\text{Wsdn}(G[n, \gamma], \mathcal{R})$ and $\text{Ssdn}(G[n, \gamma], \mathcal{R})$, respectively.

On the other hand, the bounded versions of these parameters are defined similarly as the minimum numbers of the size or index, respectively, on the space of all k -bounded sequential $\mathcal{R}$ -defining sets, i.e. the subsets A for which the sequential coloring algorithm $\text{OLG-}\mathcal{R}\text{-Col}(G[n], \mathcal{L}^A, t, d, \text{rounds}, \text{Done})$ succeeds and ends with $\text{Done} = \text{true}$ and $\text{rounds} \leq k$. These numbers are denoted as $\text{Wsdn}^k(G[n, \gamma], \mathcal{R})$ and $\text{Ssdn}^k(G[n, \gamma], \mathcal{R})$, respectively. Also, $\text{sds}_{\mathcal{R}}^k$, $\text{Wmsds}_{\mathcal{R}}^k$ and $\text{Smsds}_{\mathcal{R}}^k$ are defined accordingly. ♠

In what follows we consider some basic properties of these concepts.

Proposition 1. *Given any ordered t -colored graph $G[\varrho, \gamma]$, any d -bounded t -coloring rule-base $\mathcal{R}$, and $A \subset V(G)$, if the list coloring problem $(G[\varrho], \mathcal{L}^{A, \gamma}, t)$ is $(\mathcal{R}, d)$ -solvable then it is also an $(\mathcal{R}, d, \|\mathcal{L}^{A, \gamma}\| - |V(G)|)$ -solvable problem.*

Proof. Clearly, if the algorithm does not stop after $\|\mathcal{L}^{A, \gamma}\| - |V(G)|$ rounds, it means that there has been a round during which no list is changed and, since $\text{OLG-}\mathcal{R}\text{-Col}$ is a deterministic algorithm, this means that after this round no list can be changed. ■

Proposition 2. *Given any t -colored graph $G[\gamma]$, any d -bounded t -coloring structural rule-base $\mathcal{R}$, with two orderings ϱ_1 and ϱ_2 for G , if A is a $\text{Wmsds}_{\mathcal{R}}$ for $G[\varrho_1, \gamma]$, then A is also a $\text{Wmsds}_{\mathcal{R}}$ for $G[\varrho_2, \gamma]$.*

Proof. Let $S \stackrel{\text{def}}{=} ((t_i, v_i, X_i))_{i \in \{1, 2, \dots, s\}}$ be the sequence of vertices, as v_i , along with their d -neighborhoods X_i (as an ordered list-graph), such that v_i is the i 'th vertex whose list is changed (made smaller) by the algorithm

$$\text{OLG-}\mathcal{R}\text{-Col}(G[\varrho_1], \mathcal{L}^{A, \gamma}, t, d, \text{rounds}, \text{Done}).$$

at time t_i . Note that this is a well-defined sequence since by the hypothesis at least one list is changed in each round (or the algorithm will fall in a loop-state which is a contradiction).

Consider the same sequence $S' \stackrel{\text{def}}{=} ((t'_i, v'_i, X'_i))_{i \in \{1, 2, \dots, s'\}}$ for the algorithm

$$\text{OLG-}\mathcal{R}\text{-Col}(G[\varrho_2], \mathcal{L}^{A, \gamma}, t, d, \text{rounds}, \text{Done}).$$

Let f be the increasing function that presents the best-fit embedding of S in S' , i.e. $f(i)$ is the smallest index in the sequence S' such that $v'_{f(i)} = v_i$. Now since the rules in $\mathcal{R}$ does not change the set of possible colorings of the neighborhood structure they are applied to (and consequently does not change the set of possible colorings of the whole graph), each list of the graph $X'_{f(i)}$ is a subsets of the corresponding list in the graph X_i for each i . This proves that the second algorithm for $G[\varrho_2]$ will eventually reach the same coloring γ but possibly in a longer period of time bounded by the function $t'_{f(i)}$. ■

It is important to note that the condition of being structural for the rule-base in Proposition 1 can not be removed since, for instance, on $K_3[v_1, v_2, v_3]$ with v_1 colored red one can easily see that by reversing the order on the other two vertices the whole coloring is changed when using the greedy sequential algorithm.

Proposition 3. *Given any ordered t -colored graph $G[n, \gamma]$, and any d -bounded t -coloring rule-base $\mathcal{R}$, with $\text{Ssdn}(G[n], \gamma, \mathcal{R}) < \infty$, then*

- a) $\forall k \geq 1 \quad \text{Wsdn}^k(G[n], \gamma, \mathcal{R}) \leq \text{Ssdn}^k(G[n], \gamma, \mathcal{R})$.
- b) *A subset A is a $\text{Smsds}_{\mathcal{R}}^1$ for $G[n, \gamma]$ if and only if it is a $\text{Wmsds}_{\mathcal{R}}^1$, and consequently, $\text{Ssdn}^1(G[n], \gamma, \mathcal{R}) = \text{Wsdn}^1(G[n], \gamma, \mathcal{R})$.*
- c) *If $1 \leq i \leq j$ then*

$$\text{Ssdn}(G[n], \gamma, \mathcal{R}) \leq \text{Ssdn}^j(G[n], \gamma, \mathcal{R}) \leq \text{Ssdn}^i(G[n], \gamma, \mathcal{R}) \leq n.$$

Moreover, the upper bound is tight.

- d) *If $1 \leq i \leq j$ then*

$$\text{Wsdn}(G[n], \gamma, \mathcal{R}) \leq \text{Wsdn}^j(G[n], \gamma, \mathcal{R}) \leq \text{Wsdn}^i(G[n], \gamma, \mathcal{R}).$$

Moreover, if $\mathcal{R}$ is a structural rule-base then,

$$t - 1 \leq \text{Wsdn}(G[n], \gamma, \mathcal{R})$$

and the lower bound is tight.

Proof.

- a) If A is a $\text{Wmsds}_{\mathcal{R}}^k$ for $G[n, \gamma]$, then the list coloring problem $(G[n], \mathcal{L}^{A, \gamma}, t)$ is $(\mathcal{R}, d, k+1)$ -solvable. Any other set B that is an $\text{Smsds}_{\mathcal{R}}^k$ for $G[n, \gamma]$ must have a greater cardinality than A due to the definition of $\text{Wmsds}_{\mathcal{R}}^k$, since it takes at least 1 round for

$$\text{OLG-}\mathcal{R}\text{-Col}(G[n], \mathcal{L}^{B, \gamma}, t, d, \text{rounds}, \text{Done})$$

to be finished and $\iota_{G[n, \gamma], \mathcal{R}}(B) = |B| + \text{rounds} - 1$.

- b) If A is a $\text{Smsds}_{\mathcal{R}}^1$ for $G[n, \gamma]$ then the list coloring problem $(G[n], \mathcal{L}^{A, \gamma}, t)$ is $(\mathcal{R}, d)$ -solvable in exactly one round. Therefore,

$$\iota_{G[n, \gamma], \mathcal{R}}(A) = |A| + \text{rounds} - 1 = |A|$$

and from the definition, one deduces that A is also a $\text{Wmsds}_{\mathcal{R}}^1$. The converse implication follows in the same way.

- c) If A is an $\text{Smsds}_{\mathcal{R}}^k$ for $G[n, \gamma]$ then the list coloring problem $(G[n], \mathcal{L}^{A, \gamma}, t)$ is $(\mathcal{R}, d, k+1)$ -solvable. Also, note that for the empty graph of size n we have

$$\text{Ssdn}^1(\overline{K}_n[n], \gamma, \mathcal{R}_T) = n,$$

with respect to any t -coloring γ .

- d) Let A be a $\text{Wmsds}_{\mathcal{R}}$ for $G[n, \gamma]$ and the structural rule-base $\mathcal{R}$. Then, by definition $G[n, \mathcal{L}^{A, \gamma}]$ is a uniquely list t -colorable graph and consequently, $|A| \geq t-1$. Also, $\text{Wsdn}(K_3[n], \gamma, \mathcal{R}_T) = 2$ for any 3-coloring γ which shows that the inequality is sharp.

■

Definition 6. For each $k \geq 1$ the ordered marked graph $D_k[\varrho][u, v]$ is defined as follows (see Figure 2). For $k = 1$ we define,

$$D_1[\varrho][u, v, z] \stackrel{\text{def}}{=} \varepsilon[u, z] + \varepsilon[v, z], \quad (4)$$

with

$$\varrho \stackrel{\text{def}}{=} \begin{cases} \varrho(u) = 1, \\ \varrho(v) = 2, \\ \varrho(z) = 3, \end{cases}$$

and for $k \geq 2$,

$$\begin{aligned} D_k[\varrho][u, v] &\stackrel{\text{def}}{=} \varepsilon[u, z] + \varepsilon[u, x_k] + \varepsilon[v, x_k] + \varepsilon[z, x_1] \\ &+ \sum_{i=1}^{k-1} K_3[x_i, v_{1,i}, v_{2,i}] + K_3[x_{i+1}, v_{1,i}, v_{2,i}] \\ &+ \sum_{i=1}^{k-1} \varepsilon[z, v_{1,i}], \end{aligned} \quad (5)$$

with the ordering

$$\varrho \stackrel{\text{def}}{=} \begin{cases} \varrho(u) = 1, \\ \varrho(v) = 2, \\ \varrho(z) = k+3, \\ \varrho(x_i) = i+2 & \forall i, \\ \varrho(v_{1,i}) = k+2i+2 & \forall i, \\ \varrho(v_{2,i}) = k+2i+3 & \forall i. \end{cases}$$

♠

Figure 2: The graph $D_k[\varrho][u, v]$.

Definition 7. The k 'th *coloring closure* of a subset A of $G[\varrho, \gamma]$, with respect to a d -bounded t -coloring rule-base $\mathcal{R}$, denoted by $CC^k(A, G[\varrho, \gamma], \mathcal{R})$, is defined to be the induced subgraph $H[\tilde{\varrho}, \tilde{\gamma}]$ of $G[\varrho, \gamma]$ with the induced ordering $\tilde{\varrho}$, and the induced coloring $\tilde{\gamma}$, on all vertices that has a list of size one, when the algorithm

$$\text{OLG-}\mathcal{R}\text{-Col}(G[\varrho, \gamma], \mathcal{L}^{A, \gamma}, t, d, \text{rounds}, \text{Done})$$

is forced to stop after k rounds (if it has not already halted). ♠

The following corollary is a direct consequence of the definition which is stated to be used and referred to in later applications.

Corollary 1. *Given any d -bounded t -coloring rule-base $\mathcal{R}$, and a graph $G[\varrho, \gamma]$,*

- a) $CC^\infty(A, G[\varrho, \gamma], \mathcal{R})$ is well-defined.
- b) *Let $k \geq 1$ be an integer and let $V(G)$ be 2-partitioned as $V(G) = V(G_1) \cup V(G_2)$ with $V(G_1) \cap V(G_2) = \emptyset$, where $G_1[\varrho_1, \gamma_1]$ and $G_2[\varrho_2, \gamma_2]$ are induced subgraphs on $V(G_1)$ and $V(G_2)$ with the induced orderings and colorings, respectively. Moreover, assume that,*

- ★) *If A is either a $\text{Wmsds}^k(G_1[\varrho_1], \gamma_1, \mathcal{R})$, or a $\text{Wmsds}^k(G_2[\varrho_2], \gamma_2, \mathcal{R})$, then as induced subgraphs*

$$CC^k(A, G[\varrho, \gamma], \mathcal{R}) \neq G,$$

then,

$$\text{Wsdn}^k(G[n], \gamma, \mathcal{R}) > \max\{\text{Wsdn}^k(G_1[n], \gamma, \mathcal{R}), \text{Wsdn}^k(G_2[n], \gamma, \mathcal{R})\}.$$

Proof. For part (a) note that by Proposition 1 if $r_0 \stackrel{\text{def}}{=} \|\mathcal{L}^{A, \gamma}\| - |V(G)|$ we have,

$$CC^\infty(A, G[\varrho, \gamma], \mathcal{R}) = CC^{r_0}(A, G[\varrho, \gamma], \mathcal{R}).$$

Part (b) follows from the definitions and the hypothesis (★). ■

Theorem 1. *For any given integer $k \geq 2$ there exist an ordered colored graph $G[\varrho, \gamma]$ and a rule-base $\mathcal{R}$ such that,*

$$\text{Ssdn}^k(G[\varrho], \gamma, \mathcal{R}) \neq \text{Wsdn}^k(G[\varrho], \gamma, \mathcal{R}).$$

Proof. Fix $k \geq 2$ and consider the graph $D_k[\varrho][u, v]$ as defined in Definition 6 (see Figure 2). Also, consider the 3-coloring γ of D_k defined as,

$$\gamma \stackrel{\text{def}}{=} \begin{cases} \gamma(u) = 3, \\ \gamma(v) = 1, \\ \gamma(z) = 1, \\ \gamma(x_i) = 2 \quad \forall i, \\ \gamma(v_{1,i}) = 3 \quad \forall i, \\ \gamma(v_{2,i}) = 1 \quad \forall i. \end{cases}$$

Let $A_1 \stackrel{\text{def}}{=} \{u, v\}$. Then it is easy to see that the list coloring problem $(D_k[\varrho], \mathcal{L}^{A_1, \gamma}, 3)$ is $(\mathcal{R}_T, 2)$ -solvable in exactly k rounds with the coloring γ as its solution. Also, it is easy to see that the vertex v can not be colored by any one of the rules in $\mathcal{R}_T$, and consequently, must be contained in any $\text{sds}_{\mathcal{R}_T}$ of γ . Hence,

$$CC^\infty(\{v\}, D_k[\varrho], \gamma, \mathcal{R}_T) \neq D_k[\varrho] \quad \Rightarrow \quad \text{Wsdn}^k(D_k[\varrho], \gamma, \mathcal{R}_T) = 2.$$

On the other hand, note that for $A_2 \stackrel{\text{def}}{=} \{u, v, x_1\}$, the list coloring problem $(D_k[\varrho], \mathcal{L}^{A_2, \gamma}, 3)$ is $(\mathcal{R}_T, 2)$ -solvable in exactly 1 round with the coloring γ as its solution, which shows that

$$\text{Ssdn}^k(D_k[\varrho], \gamma, \mathcal{R}_T) \leq 3.$$

Again, by considering the vertex v , it is easy to see that

$$\text{Ssdn}^k(D_k[\varrho], \gamma, \mathcal{R}_T) \geq 2,$$

and that v must be in any such $\text{Smsds}_{\mathcal{R}_T}$. Moreover, it is easy to check that

$$CC^k(\{v, x\}, D_k[\varrho], \gamma, \mathcal{R}_T) \neq D_k[\varrho],$$

for any vertex $x \in V(D_k)$, which shows that

$$\text{Ssdn}^k(D_k[\varrho], \gamma, \mathcal{R}_T) = 3.$$

■

Theorem 2. *Given integers $\xi \geq 1$ and $k \geq 1$, there exist ordered colored graphs $G[\varrho, \gamma]$ and $H[\varrho', \gamma']$, and also rule-bases $\mathcal{R}$ and $\mathcal{R}'$ such that*

$$\text{Wsdn}^k(G[\varrho], \gamma, \mathcal{R}) - \text{Wsdn}^{k+1}(G[\varrho], \gamma, \mathcal{R}) = \xi,$$

and

$$\text{Ssdn}^k(H[\varrho'], \gamma', \mathcal{R}') - \text{Ssdn}^{k+1}(H[\varrho'], \gamma', \mathcal{R}') = \xi.$$

Proof. For each $\xi \geq 1$ consider the following ordered marked graph,

$$G_\xi[\rho][u, v] \stackrel{\text{def}}{=} \sum_{j=1}^{\xi} D_{k+1}^j[\varrho][u, v],$$

where each the ordering ϱ is defined in Definition 6, and the ordering ρ is given by,

$$\rho(w) \stackrel{\text{def}}{=} \begin{cases} 1 & w = u, \\ 2 & w = v, \\ (3k-1)(j-1) + \varrho(w) & \{u, v\} \not\ni w \in V(D_{k+1}^j[u, v, z]). \end{cases}$$

Also, consider the following 3-coloring γ_1 for each $D_{k+1}^j[\varrho][u, v]$,

$$\gamma_1 \stackrel{\text{def}}{=} \begin{cases} \gamma_1(u) = 3, \\ \gamma_1(v) = 1, \\ \gamma_1(z) = 1, \\ \gamma_1(x_i) = 2 \quad \forall i, \\ \gamma_1(v_{1,i}) = 3 \quad \forall i, \\ \gamma_1(v_{2,i}) = 1 \quad \forall i. \end{cases}$$

Define the coloring γ on $G_\xi[\rho]$ to be the coloring whose restriction on each copy of $D_{k+1}^j[\varrho][u, v]$ is γ_1 . By considering the vertex v and the fact that it must be contained in any $\text{sds}_{\mathcal{R}_T}$ for γ , one may check that

$$\text{Wsdn}^{k+1}(G_\xi[\rho], \gamma, \mathcal{R}_T) \geq 2.$$

Also, by setting $A = \{u, v\}$, it is easy to see that the list coloring problem $(G_\xi[\rho], \mathcal{L}^{A, \gamma}, 3)$ is $(\mathcal{R}_T, 2)$ -solvable in exactly $k+1$ round and returns the coloring γ as its solution, which proves that A is a $\text{Wmsds}^{k+1}(G_\xi[\rho], \gamma, \mathcal{R}_T)$, and consequently,

$$\text{Wsdn}^{k+1}(G_\xi[\rho], \gamma, \mathcal{R}_T) = 2.$$

On the other hand, we prove $\text{Wsdn}^k(G_\xi[\rho], \gamma, \mathcal{R}_T) = \xi + 2$, using induction on ξ . For the initial case $\xi = 1$ we must prove that

$$\text{Wsdn}^k(D_{k+1}[\varrho], \gamma_1, \mathcal{R}_T) = 3,$$

which follows from the facts that

$$\forall z \in V(D_{k+1}) \quad CC^k(\{v, z\}, D_{k+1}[\varrho, \gamma_1], \mathcal{R}_T) \neq D_{k+1}[\varrho, \gamma_1],$$

and

$$CC^k(\{v, u, x_1\}, D_{k+1}[\varrho, \gamma_1], \mathcal{R}_T) = D_{k+1}[\varrho, \gamma_1].$$

Therefore, we assume that the claim is true for $\xi = t$, i.e.

$$\text{Wsdn}^k(G_t[\rho], \gamma, \mathcal{R}_T) = t + 2.$$

Let X_1 be the induced subgraph of $G_{t+1}[\rho, \gamma]$ on the vertex set of the copy $G_t[\rho, \gamma]$, and also let X_2 be the the induce subgraph, formed on the vertices

$V(G_{t+1}[\rho, \gamma]) - V(X_1)$. Note that these two subgraphs satisfy the conditions of Corollary 1 and let B_1 be a $\text{Wmsds}^k(X_1, \gamma|_{X_1}, \mathcal{R}_T)$. Then it is easy to check that

$$CC^k(B_1, G_{t+1}[\rho, \gamma], \mathcal{R}_T) \subsetneq G_{t+1}[\rho, \gamma].$$

Hence, since by induction hypothesis we have

$$\text{Wsdn}^k(X_1, \gamma|_{X_1}, \mathcal{R}_T) = t + 2$$

and $\text{Wsdn}^k(X_2, \gamma|_{X_2}, \mathcal{R}_T)$ is at least equal to 1, by Corollary 1 we have

$$\text{Wsdn}^k(G_{t+1}[\rho], \gamma, \mathcal{R}_T) > \max\{t + 2, 1\} = t + 2.$$

On the other hand, by taking $B_2 \stackrel{\text{def}}{=} B_1 \cup \{x_1^{t+1}\}$, the list coloring problem $(G_{t+1}[\rho], \mathcal{L}^{B_2, \gamma}, 3)$ is $(\mathcal{R}_T, 2, k + 1)$ -solvable, which shows that

$$\text{Wsdn}^k(G_{t+1}[\rho], \gamma, \mathcal{R}_T) = t + 3,$$

and the induction is complete.

For the second part, first we prove the following,

- **Claim 1.** Let $A \subseteq V(G_\xi[\rho, \gamma])$ be such that the list coloring problem $(G_\xi[\rho], \mathcal{L}^{A, \gamma}, 3)$ is $(\mathcal{R}_T, 2, k + 1)$ -solvable, then $|A| \geq \xi + 2$.

We prove this by induction on ξ . For $\xi = 1$ it is easy to see that

$$CC^k(\{v\}, D_{k+1}[\rho, \gamma_1], \mathcal{R}_T) = \{v\}.$$

Also, note that for every $x \in V(D_{k+1})$, if $A = \{v, x\}$ then

$$CC^k(\{v, x\}, D_{k+1}[\rho, \gamma_1], \mathcal{R}_T) \subsetneq D_{k+1}[\rho, \gamma_1],$$

while for $A = \{u, v, x_1\}$ we have,

$$CC^1(A, D_{k+1}[\rho, \gamma_1], \mathcal{R}_T) = D_{k+1}[\rho, \gamma_1],$$

which shows that $|A| \geq 3$.

Hence, let the claim be true for any $\xi \leq s$. For $\xi = s + 1$ let G_{s+1} be partitioned into X_1 a copy of G_s , and $X_2 \stackrel{\text{def}}{=} G_{s+1} - G_s$. Now, by the induction hypothesis and Corollary 1, any $\text{sds}^k(X_1, \gamma|_{X_1}, \mathcal{R}_T)$ is of size at least $s + 2$. Since any such set for X_2 has at least one vertex, and one can verify that the hypothesis of Corollary 1 is satisfied, we have

$$|A| \geq \text{Wsdn}^k(G_{s+1}, \gamma, \mathcal{R}_T) \geq s + 3 = \xi + 2.$$

As a direct consequence of this claim we have

$$\text{Ssdn}^k(G_{\xi+k}[\rho], \gamma, \mathcal{R}_T) \geq \xi + k + 2,$$

and the fact that for $A \stackrel{\text{def}}{=} \{u, v, x_1^1, \dots, x_1^{\xi+k}\}$ the list coloring problem $(G_{\xi+k}[\rho], \mathcal{L}^{A, \gamma}, 3)$ is $(\mathcal{R}_T, 2)$ -solvable, in k rounds, shows that equality holds and we actually have,

$$\text{Ssdn}^k(G_{\xi+k}[\rho], \gamma, \mathcal{R}_T) = \xi + k + 2.$$

Moreover, we show that

$$\text{Ssdn}^{k+1}(G_{\xi+k}[\rho], \gamma, \mathcal{R}_T) = k + 2.$$

For this, again, by considering the coloring properties of the vertex v and the set $A = \{u, v\}$, it is easy to see that the list coloring problem $(G_{\xi+k}[\rho], \mathcal{L}^{A, \gamma}, 3)$ is $(\mathcal{R}_T, 2)$ -solvable, in exactly $k + 1$ rounds and returns the coloring γ , which shows that

$$\text{Ssdn}^{k+1}(G_{\xi+k}[\rho], \gamma, \mathcal{R}_T) \leq k + 2.$$

To prove equality, by contradiction, let's assume that A_1 is an arbitrary set such that the list coloring problem $(G_{\xi+k}[\rho], \mathcal{L}^{A_1, \gamma}, 3)$ is $(\mathcal{R}_T, 2, k + 2)$ -solvable, with

$$\iota_{G_{\xi+k}[\rho], \gamma, \mathcal{R}_T}(A_1) < k + 2.$$

- **Claim 2.** The list coloring problem $(G_{\xi+k}[\rho], \mathcal{L}^{A_1, \gamma}, 3)$ is $(\mathcal{R}_T, 2, k + 1)$ -solvable, i.e. $\text{rounds} \leq k$.

For this, again note that,

$$CC^k(\{v\}, G_{\xi+k}[\rho, \gamma], \mathcal{R}_T) = \{v\},$$

and as in the previous case, $|A_1| \geq 2$ with $v \in A_1$, which shows that

$$2 + \text{rounds} - 1 \leq |A_1| + \text{rounds} - 1 < k + 2 \Rightarrow \text{rounds} \leq k.$$

Therefore, using Claim 1 we deduce,

$$\iota_{G_{\xi+k}[\rho], \gamma, \mathcal{R}_T}(A_1) \geq |A_1| \geq \xi + k + 2 > k + 2,$$

which is a contradiction. ■

3 Some complexity results

In this section we consider a couple of basic computational problems related to defining sets of sequential coloring of graphs and we settle their computational complexity in the class of **NP**-complete problems. It should be noted that similar results in the case of *greedy online coloring* of graphs have already been settled by M. Zaker (see [28, 29, 30, 31]). In this article we have considered the more general setup of *sequential coloring* of graphs which asks for new proofs, even in the case of greedy algorithms, however, in what follows we not only state and prove our theorems in this general framework, but also we focus our proofs on the case of *structural* rule-bases to show that the **NP**-completeness results are true even in this more restricted case.

Also, we would like to mention, in spite of the fact that we have not been able to present concise **NP**-completeness proofs that hold for any given rule-base, but we conjecture that our results are true for any such nontrivial rule-base in general. Our results in this regard, (Theorem 3(b) and Theorem 5) can be considered as justifications of this conjecture, where one should note that the condition of having the rule R_1^{Tu} in the rule-base, is just a bit stronger than the natural condition of having $R_1^{Tu}(2)$ as a necessary condition.

To begin let us consider the 3-colorability problem as follows,

Problem 1. (3COL)

Given: A graph G .

Query: Is G 3-colorable?

which is used to prove the **NP**-completeness of the following problems as it is stated in the next forthcoming theorem.

Problem 2. (COLWDS $_{\mathcal{R}}^k$)

Constant: A d -bounded t -coloring rule-base $\mathcal{R}$ and an integer $k \geq 1$.

Given: An ordered graph $G[n]$, and an integer $\xi \geq 1$.

Query: Is it true that there exists a t -coloring γ such that $Wsdn^k(G[n], \gamma, \mathcal{R}) \leq \xi$?

Problem 3. (COLSDS $_{\mathcal{R}}^k$)

Constant: A d -bounded t -coloring rule-base $\mathcal{R}$ and an integer $k \geq 1$.

Given: An ordered graph $G[n]$, and an integer $\xi \geq 1$.

Query: Is it true that there exists a t -coloring γ such that $Ssdn^k(G[n], \gamma, \mathcal{R}) \leq \xi$?

Theorem 3.

- a) For every integer $k \geq 1$, both problems **COLWDS $_{\mathcal{R}_T}^k$** and **COLSDS $_{\mathcal{R}_T}^k$** are **NP**-complete.
- b) For every d -bounded 3-coloring structural rule-base $\mathcal{R}$ that contains Tucker's first rule R_1^{Tu} , both problems **COLWDS $_{\mathcal{R}}^1$** and **COLSDS $_{\mathcal{R}}^1$** are **NP**-complete.

Proof. To prove part (a) note that clearly both problems are in **NP**. We show that **3COL** $\leq_m^P$ **COLSDS $_{\mathcal{R}_T}^k$** and **3COL** $\leq_m^P$ **COLWDS $_{\mathcal{R}_T}^k$** .

Let $G = (V(G), E(G))$ be a 3-colorable ordered graph with $|V(G)| = n$, vertex ordering ς and the edge ordering ϵ . We construct the new graph $\tilde{G}$ by substituting every edge uv of G by a copy of $\sum_{i=1}^n D_k^i[u, v]$, i.e.

$$\tilde{G}[\rho] \stackrel{\text{def}}{=} \sum_{uv \in E(G)} \sum_{i=1}^n D_k^{i, \epsilon(uv)}[\varrho][u, v],$$

where $D_k^{i,j}[u, v]$'s are isomorphic copies of the graph $D_k[\varrho][u, v]$ defined in Definition 6. Also, we define the ordering ρ on vertices of $\tilde{G}$,

$$\rho(z) \stackrel{\text{def}}{=} \begin{cases} \varsigma(z) & z \in V(G), \\ n + (3k - 1)(n(j - 1) + i - 1) + \varrho(z) & \{u, v\} \not\preceq z \in V(D_k^{i,j}[u, v]), \end{cases}$$

where ϱ is as defined in Definition 6. We show that G is 3-colorable if and only if among all 3-colorings of $\tilde{G}[\rho]$, there exists a 3-coloring γ such that,

$$\text{Wsdn}^k(\tilde{G}[\rho], \gamma, \mathcal{R}_T) \leq n.$$

To see this, consider a proper 3-coloring γ_1 of G and let

$$A \stackrel{\text{def}}{=} \bigcup_{v \in V(G)} v \subseteq V(\tilde{G}).$$

Now for every $uv \in E(G)$, the 3-coloring γ_1 of G assigns colors $\gamma_1(u)$ and $\gamma_1(v)$. These colors induce a coloring $\gamma_{\gamma_1(u), \gamma_1(v)}$ on the graph $\sum_{i=1}^n D_k^{i, \epsilon(uv)}[\varrho][u, v]$. This can easily be verified from the Definition 6. Define γ on vertices of $\tilde{G}[\varrho]$, to be the accumulation of all such induced colorings:

$$\gamma(z) \stackrel{\text{def}}{=} \begin{cases} \gamma_1(z) & z \in V(G), \\ \gamma_{\gamma_1(u), \gamma_1(v)} & z \notin V(G) \text{ \& } z \in V(\sum_{i=1}^n D_k^{i, \epsilon(uv)}[\varrho][u, v]), \end{cases}$$

It is easy to verify that the list coloring problem $(\tilde{G}[\rho, \gamma], \mathcal{L}^{A, \gamma}, 3)$ is $(\mathcal{R}_T, 2)$ -solvable, in exactly k rounds and returns the coloring γ , which shows that A is a $\text{sds}^k(\tilde{G}[\rho], \gamma, \mathcal{R}_T)$, and consequently,

$$\text{Wsdn}^k(\tilde{G}[\rho], \gamma, \mathcal{R}_T) \leq |A| = n.$$

On the other hand, if G is not 3-colorable, then for every 3-coloring γ_2 of G , there exists an edge $xy \in E(G)$ such that $\gamma_2(x) = \gamma_2(y)$. But since $\mathcal{R}_T$ is a structural rule-base, it is easy to see that

$$CC^k(\{x, y\}, \tilde{G}[\rho, \gamma_2], \mathcal{R}_T) = \tilde{G}|_{\{x, y\}} \simeq \overline{K}_2,$$

which means that the algorithm can not color the structure between x and y . Now, the same kind of induction used in Theorem 2 can be used to show that every $\text{sds}_{\mathcal{R}_T}$ for $\tilde{G}[\rho, \gamma_2]$ needs at least one vertex in each copy of D_k , to prove that

$$\text{Wsdn}^k(\tilde{G}[\rho], \gamma_2, \mathcal{R}_T) > n,$$

which is a contradiction.

For the case of Ssdn^k , using the same approach as in the previous case, we define

$$\tilde{H}[\rho'] \stackrel{\text{def}}{=} \sum_{uv \in E(G)} \sum_{i=1}^{n+k} D_k^{i, \epsilon(uv)}[\varrho][u, v],$$

with ordering ρ' , which is defined in the similar fashion that ρ was defined. One may prove that G is 3-colorable if and only if among all 3-colorings of $\tilde{H}[\rho']$, there exists a 3-coloring γ such that,

$$\text{Ssdn}^k(\tilde{H}[\rho'], \gamma, \mathcal{R}_T) \leq n + k - 1,$$

and this completes the proof of part (a).

Part (b) can also be proved using the same method along with part (b) of Proposition 3, using the graph

$$\tilde{N} \stackrel{\text{def}}{=} \sum_{uv \in E(G)} \sum_{i=1}^n D_1^i[u, v].$$

■

In what follows we focus on the following problems which are natural specialization of the previous problems to colored graphs.

Problem 4. ($\text{WDS}_{\mathcal{R}}^k$)

Constant: A d -bounded t -coloring rule-base $\mathcal{R}$ and an integer $k \geq 1$.

Given: An ordered colored graph $G[n, \gamma]$, and an integer $\xi \geq 1$.

Query: Is it the case that $\text{Wsdn}^k(G[n], \gamma, \mathcal{R}) \leq \xi$?

Problem 5. ($\text{SDS}_{\mathcal{R}}^k$)

Constant: A d -bounded t -coloring rule-base $\mathcal{R}$ and an integer $k \geq 1$.

Given: An ordered colored graph $G[n, \gamma]$, and an integer $\xi \geq 1$.

Query: Is it the case that $\text{Ssdn}^k(G[n], \gamma, \mathcal{R}) \leq \xi$?

Given a graph $G = (V(G), E(G))$, a (vertex) *covering set* $S \subseteq V(G)$ is a subset of vertices such that every edge in $E(G)$ is incident to at least one vertex in S . In this regard one may consider the following problem,

Problem 6. (VertexCover)

Given: A graph G and an integer ξ .

Query: Does G have a covering set of size at most ξ ?

Let us also define a couple of graphs as follows.

Definition 8. For each $k \geq 2$ we define the ordered colored graph $F_k[\mu, \psi][u, v, x, y]$ as follows (see Figure 3),

$$\begin{aligned} F_k[\mu, \psi][u, v, x, y] &\stackrel{\text{def}}{=} \varepsilon[z_1, x] + \varepsilon[\tilde{z}_1, y] + \varepsilon[z_1, v] + \varepsilon[\tilde{z}_1, v] + \varepsilon[u, z_3] \\ &\quad + \varepsilon[u, \tilde{z}_3] + \varepsilon[u, z_5] + \varepsilon[u, \tilde{z}_5] \\ &\quad + K_3[z_1, z_2, z_3] + K_3[\tilde{z}_1, \tilde{z}_2, \tilde{z}_3] + K_3[z_4, z_2, z_3] + K_3[\tilde{z}_4, \tilde{z}_2, \tilde{z}_3] \\ &\quad + K_3[z_5, z_4, y] + K_3[\tilde{z}_5, \tilde{z}_4, x] \\ &\quad + \sum_{i=1}^{k-1} (K_3[y_i, x_{1,i}, x_{2,i}] + K_3[y_{i+1}, x_{1,i}, x_{2,i}]) \\ &\quad + \sum_{i=1}^{k-1} (\varepsilon[u, x_{1,i}]) \\ &\quad + \varepsilon[x, y_k] + \varepsilon[y, y_k] + \varepsilon[v, y_k], \end{aligned}$$

with the ordering

$$\mu \stackrel{\text{def}}{=} \begin{cases} \mu(u) = 1, \mu(v) = 2, \\ \mu(x) = 3, \mu(y) = 4, \\ \mu(z_1) = 5, \mu(\tilde{z}_1) = 6, \\ \mu(z_4) = 7, \mu(\tilde{z}_4) = 8, \\ \mu(z_5) = 9, \mu(\tilde{z}_5) = 10, \\ \mu(z_3) = 11, \mu(\tilde{z}_3) = 12, \\ \mu(z_2) = 13, \mu(\tilde{z}_2) = 14, \\ \mu(y_i) = 15 + (i - 1) & \forall i, \\ \mu(x_{1,i}) = 15 + k + 2(i - 1) & \forall i, \\ \mu(x_{2,i}) = 16 + k + 2(i - 1) & \forall i, \end{cases}$$

and the coloring (as depicted in Figure 3)

$$\psi \stackrel{\text{def}}{=} \begin{cases} \psi(u) = 1, \psi(v) = 2, \\ \psi(x) = 1, \psi(y) = 1, \\ \psi(z_1) = 3, \psi(\tilde{z}_1) = 3, \\ \psi(z_4) = 3, \psi(\tilde{z}_4) = 3, \\ \psi(z_5) = 2, \psi(\tilde{z}_5) = 2, \\ \psi(z_3) = 2, \psi(\tilde{z}_3) = 2, \\ \psi(z_2) = 1, \psi(\tilde{z}_2) = 1, \\ \psi(y_i) = 3 & \forall i, \\ \psi(x_{1,i}) = 2 & \forall i, \\ \psi(x_{2,i}) = 1 & \forall i. \end{cases}$$

Theorem 4. *Given an integer $k \geq 2$, both problems $\mathbf{SDS}_{\mathcal{R}_T}^k$ and $\mathbf{WDS}_{\mathcal{R}_T}^k$ are NP-complete.*

Proof. It is clear that both problems $\mathbf{SDS}_{\mathcal{R}_T}^k$ and $\mathbf{WDS}_{\mathcal{R}_T}^k$ are in **NP** for any $k \geq 2$. To prove the completeness we show that $\mathbf{VertexCover} \leq_m^P \mathbf{SDS}_{\mathcal{R}_T}^k$. The other case $\mathbf{VertexCover} \leq_m^P \mathbf{WDS}_{\mathcal{R}_T}^k$ can be proved using a similar argument.

Let $G = (V(G), E(G))$ and an integer t constitute an instance of **VertexCover** with $|V(G)| = n$. We construct an ordered colored graph $\tilde{G}[\rho, \psi_1]$ and an integer $\tilde{t} = t + k + 1$ that constitute an instance of $\mathbf{SDS}_{\mathcal{R}_T}^k$ such that G admits a vertex-cover of size at most t if and only if

$$\mathbf{Ssdn}^k(\tilde{G}[\rho], \psi_1, \mathcal{R}_T) \leq \tilde{t} = t + k + 1.$$

For this, assume the vertex ordering ς , and an edge ordering ϵ on the vertices and edges of G , respectively, and also choose two new vertices $u \notin V(G)$, $v \notin V(G)$ and define,

$$\tilde{G} \stackrel{\text{def}}{=} \sum_{xy \in E(G)} \sum_{i=1}^{n+k+2} F_k^{i, \epsilon(xy)}[\mu, \psi][u, v, x, y],$$

Figure 3: The graph $F_k[\mu, \psi][u, v, x, y]$.

where each $F_k^{i, \epsilon(xy)}[\mu, \psi][u, v, x, y]$ is a copy of the graph $F_k[\mu, \psi][u, v, x, y]$ defined in Definition 8. Moreover, we define the ordering ρ on $V(\tilde{G})$ as follows,

$$\rho(z) \stackrel{\text{def}}{=} \begin{cases} 1 & z = u, \\ 2 & z = v, \\ \varsigma(z) & z \in V(G), \\ n + \mu(z) - 2 + (3k + 8)[(n + k + 2)(\epsilon(xy) - 1) + i - 1] & \begin{aligned} &z \notin \{u, v\} \text{ \& } \\ &z \notin V(G) \text{ \& } \\ &z \in V(F_k^{i, \epsilon(xy)}[\mu, \psi][u, v, x, y]), \end{aligned} \end{cases}$$

as well as the coloring ψ_1 of $G[\rho]$ as,

$$\psi_1(z) \stackrel{\text{def}}{=} \begin{cases} 1 & z = u, \\ 2 & z = v, \\ 1 & z \in V(G), \\ \psi(z) & z \in V(F_k^{i, \epsilon(xy)}[\mu][u, v, x, y]). \end{cases}$$

Now, consider a vertex covering set A of G with $|A| \leq t$. First, note that the list coloring problem $(F_k^i[\mu, \psi], \mathcal{L}^{\{z, u, v\}, \psi}, 3)$ is $(\mathcal{R}_T, 2)$ -solvable in k rounds. Therefore, for $A_1 \stackrel{\text{def}}{=} A \cup \{u, v\}$ as a defining set, the algorithm

$$\mathbf{OLG-R}_T\text{-Col}(\tilde{G}[\rho, \psi_1], \mathcal{L}^{A_1, \psi_1}, 3, 2, \text{rounds}, \text{Done})$$

stops with $\text{Done} = \text{true}$ and $\text{rounds} = k$ resulting in coloring ψ_1 , which shows that A_1 is a $\text{sds}^k(\tilde{G}[\rho], \psi_1, \mathcal{R}_T)$, and consequently,

$$\text{Ssdn}^k(\tilde{G}[\rho], \psi_1, \mathcal{R}_T) \leq t + k + 1.$$

On the other hand, assume that A is a $\text{Smsds}^k(\tilde{G}[\rho], \psi_1, \mathcal{R}_T)$ of index less than or equal to $t + k + 1$ for $\tilde{G}$.

- **Claim 1.** If $(\tilde{G}[\rho, \psi_1], \mathcal{L}^{A, \psi_1}, 3)$ is $(\mathcal{R}_T, 2, k)$ -solvable then the intersection of A with $V(\sum_{i=1}^{n+k+2} F_k^{i, \epsilon(xy)}[\mu, \psi][u, v, x, y]) - \{u, v, x, y\}$ for each edge xy , is of size at least $n + k + 2$.

To prove this, one may use a similar induction as used in Theorem 2 to show that the intersection of A with each component is nonempty.

- **Claim 2.** The algorithm $\mathbf{OLG-R}_T\text{-Col}(\tilde{G}[\rho, \psi_1], \mathcal{L}^{A, \psi_1}, 3, 2, \text{rounds}, \text{Done})$ stops in exactly k rounds. Because, if this is not the case, then by Claim 1,

$$\iota_{\tilde{G}[\rho, \psi_1], \mathcal{R}_T}(A) \geq |A| \geq |E(G)|(n + k + 2) > t + k + 1,$$

which is a contradiction.

- **Claim 3.** We show that there exists another $\text{sds}^k(\tilde{G}[\rho], \psi_1, \mathcal{R}_T)$, say B , of index less than or equal $t + k + 1$ such that $B \subseteq V(G) \cup \{u, v\}$.

For this let

$$S_{xy} \stackrel{\text{def}}{=} A \cap \left(V \left(\sum_{i=1}^{n+k+2} F_k^{i, \epsilon(xy)}[\mu, \psi][u, v, x, y] \right) - \{u, v\} \right).$$

It is easy to see that $|S_{xy}| \leq 2$, since if $|S_{xy}| > 2$ for an edge xy , then one may exclude all vertices of S_{xy} from A and add x and y to obtain a new $\text{sds}^k(\tilde{G}[\rho], \psi_1, \mathcal{R}_T)$, A' , with a smaller index, which is a contradiction.

Hence, if $|S_{xy}| = 2$ for an edge xy , we may form the new set $A' \stackrel{\text{def}}{=} (A - S_{xy}) \cup \{x, y\}$ to obtain a new $\text{sds}^k(\tilde{G}[\rho], \psi_1, \mathcal{R}_T)$ with the same index.

Also, if $|S_{xy}| = 1$ for an edge xy , one may form the set $A' \stackrel{\text{def}}{=} (A - S_{xy}) \cup \{z\}$, where z is the first vertex in $\{x, y\}$ whose color is fixed when the algorithm

OLG- $\mathcal{R}_T$ -Col is coloring the graph $\tilde{G}$. Note that, the structure of F_k ensures that the colors of x and y can not be set in the same round of the sequential coloring algorithm using only one vertex in S_{xy} . Also, the mapping for the case $|S_{xy}| = 1$ is one-to-one, since otherwise, again by replacement, one obtains a sds^k with a smaller index which is a contradiction.

Applying this procedure for all edges of G will give rise to a $\text{sds}^k(\tilde{G}[\rho], \psi_1, \mathcal{R}_T)$, B , with the same index as A .

- **Claim 4.** For each edge xy , we have $|S_{xy}| \neq 0$.

This is clear, since otherwise, the graph $\sum_{i=1}^{n+k+2} F_k^{i, \epsilon(xy)}[\mu, \psi][u, v, x, y]$ can not be colored in k rounds, i.e.

$$CC^k(B, \tilde{G}[\rho, \psi_1], \mathcal{R}_T) \neq \tilde{G}[\rho, \psi_1].$$

Clearly, Claim 4 shows that $B - \{u, v\}$ is a vertex covering set of G with

$$|B - \{u, v\}| \leq (t + k + 1) - \text{rounds} + 1 - 2 = t.$$

■

Now we try to generalize the previous result to any structural rule-base. In this regard we define,

Definition 9. For each $n \geq 2$ we define the ordered colored graph $H_n[\omega, \eta][x, y, v]$ as follows (see Figure 4).

$$\begin{aligned} H_n[\omega, \eta][x, y, v] &\stackrel{\text{def}}{=} \sum_{i=1}^n (K_3[x, u_{1,i}, u_{2,i}] + K_3[y, u_{1,i}, u_{2,i}]) \\ &\quad + \sum_{i=1}^n \varepsilon[v, u_{1,i}], \end{aligned} \tag{6}$$

with the ordering,

$$\omega \stackrel{\text{def}}{=} \begin{cases} \omega(v) = 1, \\ \omega(x) = 2n + 2, \\ \omega(y) = 2n + 3, \\ \omega(u_{1,i}) = 2i & \forall i, \\ \omega(u_{2,i}) = 2i + 1 & \forall i, \end{cases}$$

and the coloring (as depicted in Figure 4)

$$\eta \stackrel{\text{def}}{=} \begin{cases} \eta(v) = 3, \\ \eta(x) = 1, \\ \eta(y) = 1, \\ \eta(u_{1,i}) = 2 & \forall i, \\ \eta(u_{2,i}) = 3 & \forall i. \end{cases}$$

♠

Figure 4: The graph $H_n[\omega, \eta][x, y, v]$.

Theorem 5. *For every d -bounded 3-coloring structural rule-base $\mathcal{R}$ that contains Tucker's first rule R_1^{Tu} , both problems $\mathbf{WDS}_{\mathcal{R}}^1$ and $\mathbf{SDS}_{\mathcal{R}}^1$ are NP-complete.*

Proof. It is clear that $\mathbf{SDS}_{\mathcal{R}_T}^1$ and $\mathbf{WDS}_{\mathcal{R}_T}^1$ for $k \geq 2$ are in NP. Also, using part (b) of Proposition 3, it is sufficient to show that

$$\mathbf{VertexCover} \leq_m^P \mathbf{SDS}_{\mathcal{R}}^1 = \mathbf{WDS}_{\mathcal{R}}^1.$$

Let $G = (V(G), E(G))$ and an integer t constitute an instance of **VertexCover** with $|V(G)| = n$. We construct an ordered colored graph $\tilde{G}[\rho, \eta_1]$ and an integer $\tilde{t} = t + 1$ that constitute an instance of $\mathbf{SDS}_{\mathcal{R}}^1$ such that G admits a vertex-cover of size at most t if and only if

$$\mathbf{Wsdn}^1(\tilde{G}[\rho, \eta_1, \mathcal{R}]) \leq \tilde{t} = t + 1.$$

Since the proof is more or less the same as the previous proof of Theorem 4, we just introduce the necessary data and an sketch of the necessary steps. For this, assume the vertex ordering ς , and an edge ordering ϵ on the vertices and the edges of G , respectively. Choose a new vertex $v \notin V(G)$ and define,

$$\tilde{G} \stackrel{\text{def}}{=} \sum_{xy \in E(G)} H_n^{\epsilon(xy)}[\omega, \eta][x, y, v].$$

Also, define the ordering ρ on $V(\tilde{G})$,

$$\rho(z) \stackrel{\text{def}}{=} \begin{cases} 1 & z = v, \\ 2n|E(G)| + 1 + \varsigma(z) & z \in V(G), \\ 1 + (2n(\epsilon(xy) - 1)) + \omega(z) & z \notin \{v, x, y\} \text{ \& } \\ & z \in V(H_n^{\epsilon(xy)}[\omega, \eta][x, y, v]). \end{cases}$$

as well as the coloring η_1 of $G[\rho]$ as,

$$\eta_1(z) \stackrel{\text{def}}{=} \begin{cases} 3 & z = v, \\ 1 & z \in V(G), \\ \eta(z) & z \notin \{x, y\} \text{ \& } \\ & z \in V(H_k^{\epsilon(xy)}[\rho][x, y, v]). \end{cases}$$

Now, consider a vertex cover A of G with $|A| \leq t$, and note that $A_1 \stackrel{\text{def}}{=} A \cup \{v\}$ will constitute a $\text{sds}^1(\tilde{G}[\rho], \eta_1, \mathcal{R}_T)$ whose size is less than or equal to $t + 1$.

One may also prove the other side using the same method used in Theorem 4. $\blacksquare$

4 Appendix: graph amalgams

Following [12], and what we discussed in Section 1, note that if $\varsigma : X \longrightarrow Y$ is a (not necessarily one-to-one) map, then one can obtain a new marked graph (Y, H, τ) by considering the push-out of the diagram

$$Y \xleftarrow{\varsigma} X \xrightarrow{\varrho} G$$

in the category of graphs. It is easy to check that the push-out exists and is a monomorphism. Also, it is easy to see that the new marked graph (Y, H, τ) can be obtained from (X, G, ϱ) by identifying the vertices in each inverse-image of ς . Hence, again (by abuse of language) we may denote (Y, H, τ) as $G[\varsigma(x_1), \varsigma(x_2), \dots, \varsigma(x_k)]$ where we allow repetition in the list appearing in the brackets. Note that with this notation one may interpret x_i 's as a set of *variables* in the *graph structure* $G[x_1, x_2, \dots, x_k]$, such that when one assigns other (new and not necessarily distinct) *values* to these variables one can obtain some other graphs (by identification of vertices).

On the other hand, given two marked graphs (X, G, ϱ) and (Y, H, τ) with $X = \{x_1, x_2, \dots, x_k\}$ and $Y = \{y_1, y_2, \dots, y_l\}$, one can construct their amalgam $(X, G, \varrho) + (Y, H, \tau)$ by forming the push-out of the following diagram,

$$H \xleftarrow{\tilde{\tau}} X \cap Y \xrightarrow{\tilde{\varrho}} G,$$

in which $\tilde{\tau} \stackrel{\text{def}}{=} \tau|_{X \cap Y}$ and $\tilde{\varrho} \stackrel{\text{def}}{=} \varrho|_{X \cap Y}$. Following our previous notations we may denote the new structure by

$$G[x_1, x_2, \dots, x_k] + H[y_1, y_2, \dots, y_l]$$

if there is no confusion about the definition of mappings. Note that when $X \cap Y$ is the empty set, then the amalgam is the *disjoint union* of the two marked graphs. Also,

by the universal property of the push-out diagram, the amalgam can be considered as marked graphs marked by X , Y , $X \cup Y$ or $X \cap Y$.

Acknowledgement

Both authors wish to express their sincere thanks to M. Zaker for his invaluable comments for improvement.
